## Materials and methods

### Cohort definition

Both the original study by Shu et al. [1] and the subsequent replication and reproducibility study by Arafe et al. [2] selected patients with Parkinson’s disease (PD) from the PPMI dataset and matched their age, sex, and H&Y score from the first of two visits spanning approximately 36 months apart. For the first visit, each patient underwent an evaluation consisting of a clinical assessment and an MRI scan. They also had a follow-up clinical examination 3 years later. Patients were classified as ‘progressive’ if their H&Y score at the follow-up visit exceeded the score from 3 years prior; otherwise, they were classified as ‘stable’. Regarding inclusion criteria, Shu et al. created a cohort by limiting their selection to patients with MRI data from a Siemens Verio 3T MRI machine, incorporating restrictions on repetition time, echo time, inversion time, field of view, matrix size, and slice thickness. Their final cohort comprised 144 patients, equally distributed between progressive and stable subjects. On the other hand, rather than a single cohort, Arafe et al. constructed 5 cohorts, each consisting of 72 stable and 72 progressive subjects. One cohort aimed to replicate the

Shu et al. cohort, while the other four were designed with different levels to assess the sensitivity of model predictions to the selection process.

Like Arafe et al. and Shu et al., as part of the selection process, we filtered the subjects in the PPMI database using the following inclusion criteria:

- **C1:** patient has a diagnosis of idiopathic PD;
- **C2:** PPMI database contains records of at least 2 visits spaced approximately 3 years apart;
- **C3:** PPMI database contains a T1-weighted MRI from the first visit determined by C2;
- **C4:** PPMI database contains H&Y scores for both visits.

We assessed the impact of the MRI machine manufacturers and models on the collected image data and concluded that restrictions on these parameters could be relaxed. However, we ensured consistency across the selected subjects by standardizing the slice thickness and field strength across all MRI machines used. Consequently, our 7 cohorts have been established according to the following additional criteria:

- **C5:** all MRI machine manufacturers and models are permissible;
- **C6:** scanner restrictions: slice thickness = 1 mm and field strength = 3T;

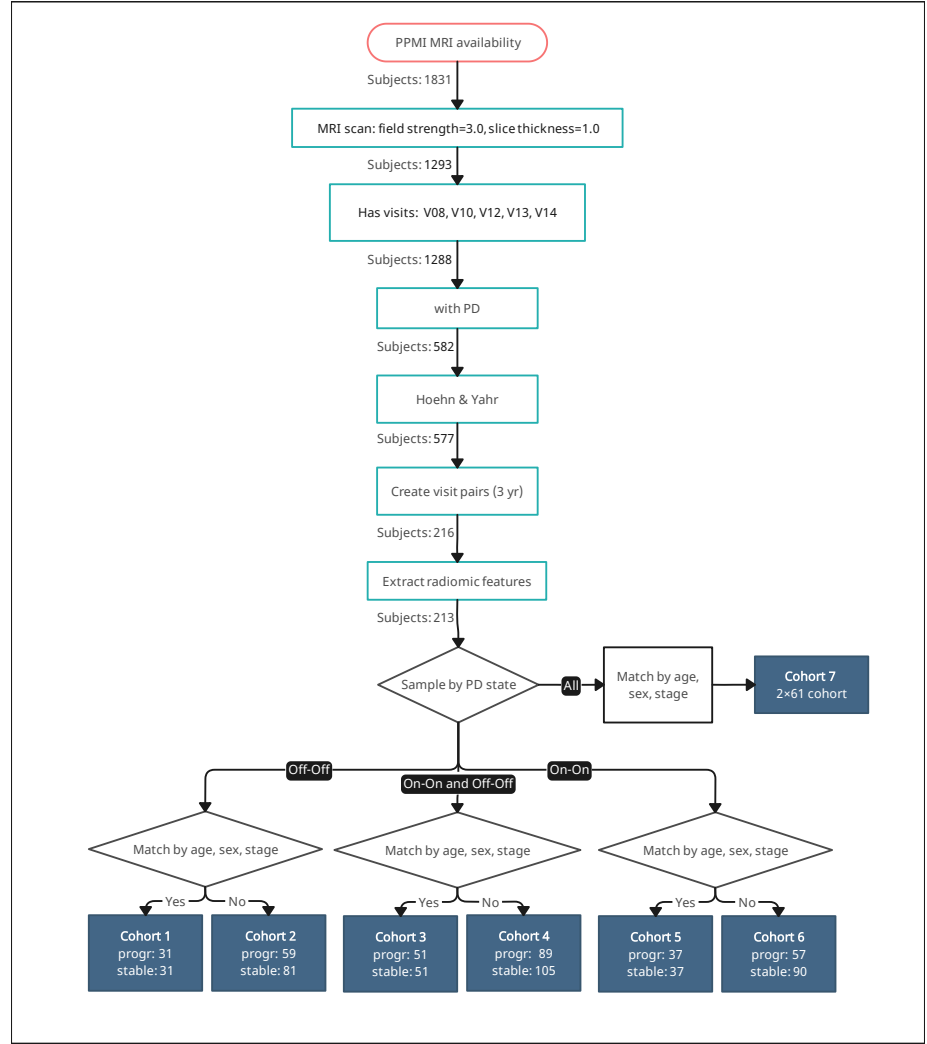

After filtering the PPMI dataset for Criteria 1 to 6, visit pairs were formed for the remaining subjects while ensuring C2 and C3 remained true for each visit pair. During this phase, an additional restriction was imposed for the formation of Cohorts 1 to 6 such that a patient’s functional state (also called PD state), which may be “On” or “Off”, must be the same for both visits. The functional state of a patient, “On” or “Off”, is determined by their PD medication status during clinical examinations. As the classification into progressive or stable groups depends on the stability of H&Y scores over time, this restriction bolsters the comparability of these scores.

As the PPMI dataset is collected over an extended period of time and the protocol requires clinical evaluation in both “On” and “Off” functional states for every visit, many subjects have more than one visit pair and it is possible for a subject to be classified as both progressive and stable for different visit pairs. Therefore, after the creation of a cohort, validation checks were defined to ensure that any given subject was only included once, as either stable or progressive, in the resulting cohort.

One of our objectives was to create the largest possible cohorts that adhered to the stated restrictions. Thus, although Cohorts 1, 3, 5, and 7 were created by matching patients from the progressive and stable classes on age, sex and H&Y scores from the first visit, Cohorts 2, 4, and 6 used no matching filter. This approach allowed for larger cohorts but necessitated the creation of demographics feature sets to evaluate the impact of this uneven distribution on the results. Cohorts 1 and 2 sampled visit pairs with PD state = “Off”, Cohorts 5 and 6 sampled pairs with PD state = “On”, and Cohorts 3 and 4 sampled visit pairs with either PD state = “Off” or PD state = “On” for both visits. Cohort 7 was defined without any restrictions on the PD state (see Fig 1).

## Feature extraction

We extracted nine sets of features for each cohort, labeled as F1 through F9. These feature sets are variations of Shu et al.’s original sets. Specifically, three sets are based on patient demographics, while the remaining six sets consist of radiomics-based features.

**Fig 1. Cohort construction** Process of filtering the PPMI dataset to construct 7 cohorts.

## Demographic features

## Radiomic features

The A.K. software (Artificial-Intelligent Radio-Genomics Kits; GE Healthcare, Chicago, IL, USA) used in Shu et al. is not publicly available. Therefore, we used PyRadiomics [3], an open-source Python package for the extraction of radiomics features. It is important to note that PyRadiomics is recognized in the IBSI (Image Biomarker Standardization Initiative) community [4].

In Shu et al., the authors extracted a total of 378 features, including 42 histograms features, 10 Haralick features, 9 FormFactor features, 126 GLCM features, 180 GLRLM features, and 11 gray level region matrix features (GLZSM). From these 378 features, the authors used the maximum relevance minimum redundancy (mRMR) algorithm to extract the following top 7 features and train the model:

- Feature 1: GLCMEntropy\_AllDirection\_offset1 76
- Feature 2: RunLengthNonuniformity\_angle45\_offset7 77
- Feature 3: Correlation\_angle45\_offset1 78
- Feature 4: HaralickCorrelation\_angle90\_offset4 79
- Feature 5: ShortRunEmphasis\_angle0\_offset7 80
- Feature 6: HaralickCorrelation\_AllDirection\_offset7 81
- Feature 7: Inertia\_AllDirection\_offset4 82

The first set of radiomic features, F4, refer to the set of PyRadiomics features that best match the 7 A.K software features from Shu et al., namely: 83 84

- Feature 1: Joint Entropy 85
- Feature 2: Run Length Non Uniformity 86
- Feature 3 / Feature 4 / Feature 6: Correlation 87
- Feature 5: Short Run Low Gray Level Emphasis 88
- Feature 7: Contrast 89

For feature sets F5 and F6, we leveraged the entire set of features extracted with PyRadiomics by applying two distinct feature selection techniques: Principal Component Analysis (PCA) for F5 and Maximum Relevance Minimum Redundancy (MRMR) for F6. Further details regarding the parameters and implementation of these techniques will be provided in subsequent sections. 90 91 92 93 94

The mapping between A.K software and PyRadiomics features is not exact. Indeed, the A.K software, unlike PyRadiomics, provides every feature at a specific angle and offset. In PyRadiomics, for each feature class, the value of a feature is calculated for each angle separately, after which the mean of these values is returned. The exact definitions of these features are available in the PyRadiomics documentation (<https://pyradiomics.readthedocs.io/en/latest/features.html>) and in the supplementary material of [1], Table S2. 95 96 97 98 99 100 101

To address this issue, we developed an extended version of PyRadiomics that allows users to request features at specific angles and offsets. Using this extension, we were able to construct three additional feature sets. The first of three feature sets, F7, consists of the 7 features found in Shu et al. using the same offset and angle. In contrast, F8 and F9 utilize all features extracted at every angle and offset, applying both PCA and MRMR to derive a final set of features. 102 103 104 105 106 107

Here is a summary of each feature set: 108

## MRI pre-processing 109

### Segmentation of T1-weighted images 110

For feature sets **F4** to **F9**, we used the Segmentation module of Statistical Parametric Mapping (SPM; <https://www.fil.ion.ucl.ac.uk/spm/software/spm12> [5]) version 12 that was also the segmentation method used in Shu et al. We used SPM12's default parameters to get the tissue probability masks and build a WM binary mask for each patient. 111 112 113 114 115

**Table 1.** Summary of the nine feature sets.

Feature Set	Summary.
F1	Patient demographics including age, sex, and H&Y score.
F2	Patient demographics including age, sex, and UPDRS score.
F3	Patient demographics including age, sex, H&Y score, and UPDRS score.
F4	PyRadiomics features aligned with Shu et al.’s A.K. Software features.
F5	PyRadiomics features with PCA feature selection.
F6	PyRadiomics features with MRMR feature selection.
F7	Angled PyRadiomics features aligned with Shu et al.’s A.K. Software features.
F8	Angled PyRadiomics features with PCA feature selection.
F9	Angled PyRadiomics features with MRMR feature selection.

**Quality control**

In Shu et al., two experienced neuro-radiologists used ITK-snap to manually edit WM segmentations. The modifications included (i) removal of non-brain tissue, brain stem and cerebellum and (ii) correcting segmentation errors in WM tissues. We used 3D Slicer v.5.0.3 to visualize and assess the quality of WM segmentations produced by SPM12. For each MRI scan, we reviewed the axial, coronal and sagittal slices. Data was excluded if it met at least one of the following criteria:

- There is WM outside of the segmented WM mask;
- There is GM inside the segmented WM mask;
- The MRI has any common artifacts;
- The MRI has a low signal-to-noise (SNR) ratio.

**Cohorts**

The demographics for Cohorts 1 to 7 are summarized in Table 2. Cohorts 1 and 2 were sampled from the same set of visit pairs, comprising a maximum of 140 subjects with PD state = “Off” for both visits. Cohort 2 randomly sampled one visit pair for each of the available subjects and distributed them to each class as evenly as possible. This resulted in 81 stable subjects and 59 progressive subjects. The mean age and standard deviation for the stable subjects is 60.5±9.6 and 62.0±9.4 for the progressive subjects. There are 32 females and 49 males in the stable group, 19 females and 40 males in the

progressive group. Regarding H&Y scores, 9 stable subjects have a score of 1, 71 a score of 2, and 1 has a score of 3. For the progressive subjects, 46 have an H&Y score = 1 and 13 have an H&Y score = 2. Cohort 1 is the smallest of the constructed cohorts with only 31 stable and 31 progressive subjects for a total of 62 subjects. The stable and progressive groups are composed of 11 females and 20 males, and 12 females and 19 males respectively. The mean age and standard deviation for the stable subjects is  $60.6 \pm 7.2$  and  $61.4 \pm 8.1$  for the progressive subjects. There are 18 subjects with H&Y score = 1 and 13 with score = 2 for both the stable and progressive groups.

Cohorts 3 and 4 sampled from a set of visit pairs for 194 subjects with either PD state = “Off” or PD state = “On” for both visits. Cohort 3 has 102 subjects with 51 subjects in each class. The stable group has 17 females and 34 males, whereas the progressive group has 19 females and 32 males. The mean age and standard deviation for the stable subjects and progressive subjects is  $60.3 \pm 8.8$  and  $62.9 \pm 8.7$  respectively. Both the stable and progressive groups have 25 subjects with H&Y score = 1 and 26 subjects with H&Y score = 2. Cohort 4 is the largest cohort and is composed of 105 stable subjects and 89 progressive subjects. The mean age and standard deviation for the stable and progressive groups are similar to one another at  $62.1 \pm 9.7$  and  $62.7 \pm 10.0$  respectively. Cohort 4 has 41 females and 64 males in the stable group, whereas the progressive group has 32 females and 57 males. The number of subjects in the stable group that have H&Y score = 1 is 11, H&Y score = 2 is 92, and H&Y score = 3 is 2. The number of subjects in the progressive group that have an H&Y score of 1, 2, or 3 are 63, 24, and 1 respectively.

Cohorts 5 and 6 sampled from the set of visit pairs defined for the 147 subjects with PD state = “On” for both visits. Cohort 5 has 74 subjects evenly distributed into stable and progressive groups of 37 each. The stable group is composed of 11 females and 26 males, and the progressive group has 14 females and 23 males. The mean age and standard deviation for the stable group is  $59.0 \pm 0.0$  and  $63.9 \pm 9.4$  for the progressive group. There are 18 subjects in each group with H&Y score = 1 and 19 subjects in each group with H&Y score = 2. Cohort 6 has 90 stable subjects and 57 progressive subjects for a total of 147 subjects. The stable group is composed of 36 females and 54 males with a mean age and standard deviation of  $63.0 \pm 9.9$ , and the progressive group has 21 females and 36 males with a mean age of  $62.9 \pm 10.1$ . The stable group has 8 subjects with H&Y score = 1, 82 subjects with H&Y score = 2, and 0 subjects with H&Y score = 3. In contrast, the progressive group has 38 subjects with H&Y score = 1, 18 subjects with H&Y score = 2, and 1 subjects with H&Y score = 3.

Cohort 7 is the only cohort that samples from a set of visit pairs for 213 subjects without any restrictions for the PD state of a patient. This cohort was developed as a reference cohort for comparison with those created by [1] and [2]. Cohort 7 has 61 stable and 61 progressive subjects for a total of 122 subjects. There are 23 females and 38 males in the stable group and 26 females and 35 males in the progressive group. The mean age and standard deviation is  $60.1 \pm 9.2$  and  $62.3 \pm 9.2$  for the stable and progressive groups respectively. The stable and progressive groups each have 35 subjects with H&Y score = 1 and 26 subjects with H&Y score = 2.

Model performance 185

Feature sets 186

Discussion 187

This section discusses the findings. 188

Conclusion 189

The conclusion is here. 190

Supporting information 191

**S1 Fig. Bold the title sentence.** Add descriptive text after the title of the item (optional). 192
